13: Local Definitions

Local definitions M13 2/42

The functions and special forms we've seen so far can be arbitrarily nested—except **define** and check-expect.

So far, definitions have to be made "at the top level", outside any expression.

The Intermediate language provides the special form **local**, which contains a series of local definitions plus an expression using them.

What use is this?

Motivating local definitions

M13 3/42

Consider Heron's formula for the area of a triangle with sides a, b, c:

$$\sqrt{s(s-a)(s-b)(s-c)}$$
, where $s=(a+b+c)/2$

It is not hard to create a Racket function to compute this function, but it is difficult to do so in a clear and natural fashion.

We will describe several possibilities, starting with a direct implementation.

```
(define (t-area-v0 a b c)
  (sqrt
  (* (/ (+ a b c) 2)
        (- (/ (+ a b c) 2) a)
        (- (/ (+ a b c) 2) b)
        (- (/ (+ a b c) 2) c))))
```

The repeated computation of s = (a + b + c)/2 is awkward.

> Motivation: rewrite expressions

M13 5/42

We could notice that s - a = (-a + b + c)/2, and make similar substitutions.

```
(define (t-area-v1 a b c)

(sqrt

(* (/ (+ a b c) 2)

(/ (+ (- a) b c) 2)

(/ (+ a (- b) c) 2)

(/ (+ a b (- c)) 2))))
```

This is slightly shorter, but its relationship to Heron's formula is unclear from just reading the code, and the technique does not generalize.

> Motivation: use a helper function (v1)

M13 6/42

We could instead use a helper function.

This generalizes well to formulas that define several intermediate quantities.

But the helper functions need parameters, which again makes the relationship to Heron's formula hard to see. And there's still repeated code and repeated computations.

We could instead move the computation using s into a helper function, and provide the value of s as a parameter.

```
(define (t-area-v3 a b c)
  (t-area/s a b c (/ (+ a b c) 2)))
(define (t-area/s a b c s)
  (sqrt (* s (- s a) (- s b) (- s c))))
```

This is more readable (it looks like Heron's formula!), shorter, and avoids recomputation, but it is still awkward because

- the value of s is defined in one function and used in another.
- t-area/s has no apparent use other than to support t-area-v3.

> Motivation: use local

M13 8/42

The **local** special form we introduced provides a natural way to bring the definition and use together.

```
(define (t-area-v4 a b c)
  (local [(define s (/ (+ a b c) 2))]
      (sqrt (* s (- s a) (- s b) (- s c)))))
```

This is nice and short!

It looks like Heron's formula.

No repeated code or computations.

Since **local** is another special form (like **cond**) that results in double parentheses, we will use square brackets to improve readability. This is another *convention*.

Reusing names

M13 9/42

Local definitions permit reuse of names. Reusing names is not new to us:

```
(define n 10)
(define (myfn n) (+ 2 n))
(myfn 6)
```

gives the answer 8, not 12.

The substitution specified in the semantics of function application ensures that the correct value is used while evaluating the last line.

Similarly, a **define** within a **local** expression may reuse a name which has already been bound to another value or expression.

The **local** substitution rules in our semantic model must handle this.

The resulting substitution rule for **local** is the most complicated one we will see in this course.

The substitution rule works by replacing every name defined in the local with a **fresh name** (a.k.a. **fresh identifier**) – a new, unique name that has not been used anywhere else in the program.

Each old name within the local is replaced by the corresponding new name.

Because the new name hasn't been used elsewhere in the program, the local definitions (with the new name) can now be "promoted" to the top level of the program without affecting anything outside of the local.

We can now use our existing rules to evaluate the program.

We will state the rule rigourously a little later.

Example 1 M13 11/42

```
(define x 5)
(define (fun a)
   (local [(define x 3)] (+ a x)))
(fun 4) ⇒

(local [(define x 3)] (+ 4 x)) ⇒

(define x_1 3)
(+ 4 x_1) ⇒
(+ 4 3) ⇒
7
```

> Example2: evaluating t-area4

M13 12/42

We'll need a fresh identifier to replace s. We'll use s_1, which we just made up.

```
 \begin{array}{l} (\text{t-area4 3 4 5}) \Rightarrow \\ (\text{local } [(\text{define } \text{s (/ (+ 3 4 5) 2)})] \\ (\text{sqrt (* s (- s 3) (- s 4) (- s 5))})) \Rightarrow \\ (\text{define } \text{s\_1 (/ (+ 3 4 5) 2)}) \\ (\text{sqrt (* s\_1 (- s\_1 3) (- s\_1 4) (- s\_1 5)})) \Rightarrow \\ (\text{define } \text{s\_1 (/ 12 2)}) \\ (\text{sqrt (* s\_1 (- s\_1 3) (- s\_1 4) (- s\_1 5)})) \Rightarrow \\ (\text{define } \text{s\_1 6}) \\ (\text{sqrt (* s\_1 (- s\_1 3) (- s\_1 4) (- s\_1 5)})) \Rightarrow \dots 6 \\ \end{array}
```

Example 3: M13 13/42

Example 4: Revising function substitution

M13 14/42

Our previous statement about using our existing rules isn't quite correct. Consider the code on the right.

Where is 2 substituted for x?

(f $v_1 \ldots v_n$) \Rightarrow exp' where (**define** (f $x_1 \ldots x_n$) exp) occurs to the left, and exp' is obtained by substituting into the expression exp, with all occurrences of the formal parameter x_i replaced by the value v_i (for i from 1 to n) except where x_i has been redefined within exp (e.g. within a local).

Example 5 M13 15/42

```
(define (foo x y)
                                                   (define x_1 3)
  (+ (local [(define x y)
                                                   (define z_1 6)
                                                   (define x_2 (* 2 3))
                (define z (+ x y))]
        (+ \times z))
                                                   (define z_2 (* x_2 3))
      (local [(define \times (* 2 y))
                                                   (+ 9 (+ x_2 z_2)) \Rightarrow ... \Rightarrow 33
                (define z (* x y))]
        (+ \times z))))
(foo 2 3) \Rightarrow \dots
(define x_1 3)
(define z_1 6)
(+ (+ x_1 z_1)
   (local
      [(define \times (* 2 3))
       (define z (* \times 3))]
      (+ \times z))) \Rightarrow \dots
```

Write a function (check-msg-length to from body min-len max-len). to, from and body are of type Str and represent a message. The length of the message is the combined lengths of to, from, and body.

min-len and max-len are Nat values representing the minimum and maximum message lengths allowed. The function produces 'too-short for messages shorter than min-len, 'too-long for messages longer than max-len, and otherwise the length of the message.

First implement this function without **local**. Then reimplement the function using **local** to avoid computing the message length multiple times.

Reasons to use local

M13 16/42

- Clarity: Naming subexpressions
 Efficiency: Avoid recomputation
 Encapsulation: Hiding stuff
 Scope: Reusing parameters

> Clarity: naming subexpressions

M13 17/42

A subexpression used twice within a function body always yields the same value.

Using local to give the reused subexpression a name improves the readability of the code.

This was a motivating factor in t-area. Naming the subexpression made the relationship to Heron's Formula clear.

```
(define (t-area-v4 a b c)
  (local [(define s (/ (+ a b c) 2))]
      (sqrt (* s (- s a) (- s b) (- s c)))))
```

Sometimes we choose to use **local** in order to give subexpressions meaningful names to make the code more readable, even if they are not reused. This may make the code longer.

> Efficiency: avoid recomputation

M13 19/42

Recall that in lecture module 09, we saw a version of max-list that used the same recursive application twice. The repeated computation of values caused it to be very slow, even for lists of length 25.

We can use local to avoid recomputation.

» Efficiency: max-list without local

M13 20/42

```
;; (max-list-v2 lon) produces the maximum element of lon
;; Examples:
(check-expect (max-list-v2 (list 6 2 3 7 1)) 7)

;; max-list-v2: (listof Num) → Num
;; Requires: lon is nonempty
(define (max-list-v2 lon)
    (cond [(empty? (rest lon)) (first lon)]
        [(> (first lon) (max-list-v2 (rest lon)))) (first lon)]
        [else (max-list-v2 (rest lon))]))
```

» Efficiency: search-bt-path: original

M13 22/42

```
;; search-bt-path: Nat BT → (anyof false (listof (anyof 'right 'left)))
(define (search-bt-path k tree)
  (cond
    [(empty? tree) false]
    [(= k (node-key tree)) empty]
    [(list? (search-bt-path k (node-left tree)))
      (cons 'left (search-bt-path k (node-left tree)))]
    [(list? (search-bt-path k (node-right tree)))
      (cons 'right (search-bt-path k (node-right tree)))]
    [else false]))
```

The efficiency problems of this code can be solved with a helper function.

» Efficiency: search-bt-path: with local

M13 23/42

This new version of search-bt-path avoids making the same recursive function application twice, and does not require a helper function.

But it still suffers from an inefficiency: we always explore the entire binary tree, even if the correct solution is found immediately in the left subtree.

We can avoid the extra search of the right subtree using nested locals.

» Efficiency: search-bt-path: with nested local

M13 25/42

> Encapsulation: hiding stuff

M13 26/42

Encapsulation is the process of grouping things together in a "capsule".

We have already seen data encapsulation in the use of structures: we grouped several fields together into one "capsule", the structure.

There is also an aspect of **information hiding** to encapsulation which we did not see with structures.

The local bindings are not visible (have no effect) outside the local expression. Thus, they can "hide" information from other parts of the program.

In CS 246 we will see how object-oriented programming combines data encapsulation (structures) with another type of encapsulation we now discuss.

Local definitions can bind names to functions as well as values. Evaluating the local expression creates new, unique names for the functions just as for the values.

This is known as **behaviour encapsulation**.

Behaviour encapsulation allows us to move helper functions within the function that uses them, so they:

- are invisible outside the function.
- do not clutter the "namespace" at the top level.
- cannot be used by mistake.

This makes the organization of the program more obvious and is particularly useful when using accumulators.

» Example: sum-list

M13 28/42

Advantages of making the accumulatively-recursive helper function local:

- It makes clear the helper has no use outside of sum-list.
- It facilitates reasoning about the program.
 In CS245 this reasoning will be extended to include invariants. They are also important in CS 240 and CS 341.

Write a function (normalize lst) that consumes a (listof Num), and returns the list containing each value in lst divided by the sum of the values in lst.

Use only local helper functions, and compute the sum only once.

(normalize (list 4 2 14)) \Rightarrow (list 0.2 0.1 0.7)

» Encapsulation and the design recipe

M13 30/42

A function can enclose the cooperating helper functions that it uses inside a **local**, as long as these are not also needed by other functions. When this happens, the enclosing function and all the helpers act as a cohesive unit.

Here, the local helper functions require contracts and purposes, but not examples or tests. The helper functions can be tested by writing suitable tests for the enclosing function.

Make sure the local helper functions are still tested completely!

» Design recipe example

M13 31/42

Mutual Recursion M13 32/42

Local can also handle mutually recursive functions.

> Scope: reusing parameters

M13 33/42

Making helper functions local can reduce the need to have parameters "go along for the ride".

» Example: countup-to-v2

M13 34/42

n no longer needs to be a parameter to countup-from, because it is in scope.

If we evaluate (countup-to-v2 10) using our substitution model, a renamed version of countup-from with n replaced by 10 is lifted to the top level.

Then, if we evaluate (countup-to-v2 20), another renamed version of countup-from is lifted to the top level.

Using only one helper function, which is local and has only one parameter, write a function (list-squares n) that produces a list containing the squares of the first n natural numbers.

```
(check-expect (list-squares 4) (list 0 1 4 9))
```

» Example: mult-table

M13 35/42

We can use the same idea to localize the helper functions for mult-table from lecture module 08.

Recall that

The c^{th} entry of the r^{th} row (numbering from 0) is $r \times c$.

» mult-table: original

M13 36/42

The implementation of mult-table2 encapsulates helper functions cols-to and rows-to using local. Modify mult-table2 to further encapsulate cols-to into rows-to. What parameters of cols-to are no longer necessary?

```
Write a function (table-ccr nr nc) that produces a table containing nr rows and nc columns, where the c^{th} entry of the r^{th} row is c^2r.

For example,

(check-expect (table-ccr 4 5)

(list (list 0 0 0 0 0)

(list 0 1 4 9 16)

(list 0 2 8 18 32)

(list 0 3 12 27 48)))

Helper functions should be encapulated within a local, of course.
```

The **binding occurrence** of a name is its use in a definition, or formal parameter to a function.

The associated **bound occurrences** are the uses of that name that correspond to that binding.

The **lexical scope** of a binding occurrence is all places where that binding has effect, taking note of holes caused by reuse of names.

Global scope is the scope of top-level definitions.

Substitution rule M13 39/42

An expression of the form (local [d_1 ... d_n] bodyexp) is rewritten as follows:

- d_i will be of the form (define x_i exp_i) or (define (x_i p_1 ... p_m) exp_i). In either case, x_i is replaced with a fresh identifier (call it x_i_new) everywhere in the local expression, for 1 ≤ i ≤ n.
- The definitions d_1 ... d_n are then lifted out (all at once) to the top level of the program, preserving their ordering.
- What remains looks like (local [] bodyexp'), where bodyexp' is the rewritten version of bodyexp. Replace the local expression with bodyexp'.

All of this (the renaming, the lifting, and removing the **local** with an empty definitions list) is a **single step**.

Conclusions M13 40/42

The use of local has permitted modest gains in expressivity and readability in our examples.

The language features discussed in the next module expand this power considerably.

Some other languages (C, C++, Java) either disallow nested function definitions or allow them only in very restricted circumstances.

Local variable and constant definitions are much more common.

- You should understand the syntax, informal semantics, and formal substitution semantics for the local special form.
- You should be able to use local to avoid repetition of common subexpressions, to improve readability of expressions, and to improve efficiency of code.
- You should understand the idea of encapsulation of local helper functions.
- You should be able to match the use of any constant or function name in a program to the binding to which it refers.

Summary: built-in functions

M13 42/42

The following functions and special forms have been introduced in this module:

local

You should complete all exercises and assignments using only these and the functions and special forms introduced in earlier modules. The complete list is:

```
* + - ... / < <= > >= abs add1 and append boolean? ceiling char-alphabetic? char-downcase char-lower-case? char-numeric? char-upcase char-upper-case? char-whitespace? char<? char<? char-? char>? char>? char? check-error check-expect check-within cond cons cons? cos define define-struct define/trace e eighth else empty? equal? error even? exp expt fifth first floor fourth integer? length list list->string list? local log max min modulo negative? not number->string number? odd? or pi positive? quotient remainder rest reverse round second seventh sgn sin sixth sqr sqrt string->list string-append string-downcase string-length string-lower-case? string-numeric? string-upcase string-upper-case? string<? string<? string=? string>? string>? string? sub1 substring symbol=? symbol? tan third zero?
```
